# Security and Authorization

Ramakrishnan & Gehrke, Chapter 21

# Overview

- Introduction
- Internet security
- Database access control
- How to hack a database

- **Secrecy:**

Users should not be able to **see** things they are not supposed to

- Ex: student can't see other students' grades

- Ex: *TJX*. owns many dept stores in US

- Attacks exploited WEP used at branches
- Over 47 million CC #s stolen dating back to 2002
- *...sue filed by consortium of 300 banks*

- Ex: *CardSystems, Inc*: US credit card payment processing company

- 263,000 CC #s stolen from database via SQL injection (June 2005)
- 43 million CC #s stored unencrypted, compromised
- *...out of business*

- **Secrecy:**

Users should not be able to **see** things they are not supposed to

- Ex: student can't see other students' grades

- Ex: *equifax*

- Collecting most sensitive citizen data for credit assessment
  - ssn, name, address, credit cards, driver's license, ...
- hacked due to insufficient internal security
  - 180m citizens affected – most US, some UK
- “all under control”
- *BTW, CEO left with 90m US\$ bonus*

- **Secrecy:**

Users should not be able to see things they are not supposed to

- Ex: student can't see other students' grades

- **Integrity:**

Users should not be able to **modify** things they are not supposed to

- Ex: Only instructors can assign grades

- **Availability:**

Users should be able to see and modify things they are allowed to

- Ex: professor can see and set students' grades (but possibly not modify after release)

# UK GCHQ Manipulating Internet [[src](#)]

- “Change outcome of online polls” (UNDERPASS)
- “Disruption of video-based websites hosting extremist content through concerted target discovery and content removal.” (SILVERLORD)
- “Active skype capability. Provision of real time call records (SkypeOut and SkypetoSkype) and bidirectional instant messaging. Also contact lists.” (MINIATURE HERO)
- “Find private photographs of targets on Facebook” (SPRING BISHOP)
- “Permanently disable a target’s account on their computer” (ANGRY PIRATE)
- “Targeted Denial Of Service against Web Servers” (PREDATORS FACE)
- “Monitoring target use of the UK eBay” (ELATE)
- “Spoof any email address and send email under that identity” (CHANGELING)
- ...

“If you don’t see it here, it doesn’t mean we can’t build it.”

# Overview

- Introduction
- Internet security
- Database access control
- How to hack a database

- Key Issues: **User authentication** and **trust**
  - For DB access from secure location, password-based schemes usually adequate
- For access over an external network, trust is hard to achieve
  - If someone with Sam's credit card wants to buy from you, how can you be sure it is not someone who stole his card?
  - How can Sam be sure that the screen for entering his credit card information is indeed yours, and not some rogue site spoofing you (to steal such information)?
  - How can he be sure that sensitive information is not “sniffed” while it is being sent over the network to you?
- **Encryption** is a technique used to address these issues

- Idea: “Mask” data for secure transmission or storage
  - $\text{Encrypt}(\text{data}, \text{encryption key}) = \text{encrypted data}$
  - $\text{Decrypt}(\text{encrypted data}, \text{decryption key}) = \text{original data}$
- **Symmetric Encryption: DES** (Data Encryption Standard)
  - Encryption key = decryption key → all authorized users know decryption key
  - DES (since 1977) 56-bit key; AES 128-bit (or 192-bit or 256-bit) key
  - 1024-bit key considered relatively safe, 2048 preferred
- **Public-Key Encryption:** Each user has **two** keys (**RSA**, Turing Award)
  - User’s encryption key: public
  - User’s decryption key: secret

# Certifying Servers: SSL, SET

- Amazon distributes their public key, Sam's browser encrypts order using it
  - So, only Amazon can decipher the order, since no one else has Amazon's private key
- **SSL protocol** to know that public key for Amazon is genuine
  - Amazon contracts with Verisign → certificate **<Verisign,Amazon,amazon.com,public-key>**
  - stored encrypted with Verisign's **private** key, known only to Verisign
  - Verisign's **public** key known to all browsers, can therefore decrypt certificate and **obtain Amazon's public key**, and **be confident** that it is genuine
  - browser generates temp **session key**, encodes it using **Amazon's public key**, sends to Amazon
  - All **subsequent messages** between the browser and Amazon are encoded using symmetric encryption (e.g., DES), which is more efficient than public-key encryption
- What if Sam doesn't trust Amazon with his credit card information?
  - **Secure Electronic Transaction (SET) protocol**:  
3-way communication between Amazon, Sam, and trusted server, e.g., Visa

# Setting Up *https* Server (Keys)

- **https** = http over **secure socket layer** (ssl) using port 443
  - `https://www.example.com/...`
  - Uses **OpenSSL**, an open-source SSL library, on server
- Create a **private key**
  - `openssl genrsa -des3 -out my.key 1024`
- Create **self-signed certificate**
  - `openssl req -new -key my.key -x509 -out my.crt`
  - browser will pop up a warning, since it cannot identify server, but communication still encrypted
- To stop this, buy an official SSL certificate
  - from Verisign or Thawte,... (\$200/year upwards)

# Setting Up *https* Server (Configuration)

JACOBS  
UNIVERSITY

- Need to tell the web server to use these
- Add the following lines to `/etc/httpd/httpd.conf`

```
<http port="443">  
  <openssl>  
    <certificate-file>keys/my.crt</certificate-file>  
    <certificate-key-file>keys/my.key</certificate-key-file>  
    <password>my-password</password>  
  </openssl>  
</http>
```

- ready to go (RTFM for your system)

# Authenticating Users

- Amazon can simply use **password authentication**
  - Sam logs into Amazon account; establishes session key via SSL → pw transmission secure (?)
  - Amazon still at risk if Sam's card stolen + password hacked. Business risk ...
- Digital Signatures:
  - Sam encrypts order using his **private key**, then encrypts result using **Amazon's public key**
  - Amazon decrypts msg with their **private key**, decrypts result using Sam's **public key**, yields original order!
  - Exploits interchangeability of public/private keys for encryption/decryption
  - Now, no one can forge Sam's order, and Sam cannot claim that someone else forged the order

# 1. Email Security

- Classic way to achieve security: email disclaimers
  - Standard legalese: *"This message is confidential. It may also be privileged or otherwise protected by work product immunity or other legal rules. If you have received it by mistake, please let us know by e-mail reply and delete it from your system; you may not copy this message or disclose its contents to anyone. Please send us by fax any message containing deadlines as incoming e-mails are not screened for response deadlines. The integrity and security of this message cannot be guaranteed on the Internet."*
  - BTW, oldest found (AD 1083): *"Si forte in alienas manus oberraverit hec peregrina epistola incertis ventis dimissa, sed Deo commendata, precamur ut ei reddatur cui soli destinata, nec preripiat quisquam non sibi parata."*
- Compare to a paper letter..
- PS: I like this one: <http://www.goldmark.org/jeff/stupid-disclaimers/>

# 1. Email Security / contd.

- “...mostly, legally speaking, pointless. Lawyers and experts on internet policy say **no court case has ever turned** on the presence or absence of such an automatic e-mail footer in America, the most litigious of rich countries.”
  - But, comment:  
„They are prevalent because in the U.S. exactly BECAUSE there is no court case that has turned on the appearance or lack of a disclaimer or end of email boiler plate. **Until a court affirmatively denies their power**, they will remain [...].”
- “Many disclaimers are, in effect, **seeking to impose a contractual obligation unilaterally**, and thus are probably unenforceable. This is clear in Europe.”
- [lifehacker.com]

**Disclaimer: this is not a legal advice, I'm not a lawyer. No responsibility whatsoever taken**

# 1. Email Security / contd.

- Risks to user
  - **Disclosure** of Information by plain text transmission
    - *Traffic analysis: in some countries emails monitored by agencies*
  - **Modification**: “man-in-the-middle attack”
  - **Masquerade**: send in the name of others
  - **Denial of Service**: overloading servers; blocking users by repeatedly wrong password
- Email encryption
  - prevent unauthorized persons to read content of email
  - PGP (Pretty Good Privacy), SecureGmail, ...

# 1. Email Security / contd.

- **Pretty Good Privacy** = Data encryption/decryption program for signing, encrypting & decrypting **emails**
  - hashing, data compression, symmetric-key cryptography & public-key cryptography
  - **public key** bound to user email & username (unique!), **published** on key server
- Ex: enigmail
  - extension for Thunderbird & Seamonkey
  - [install plugin](#), [create public key](#), [publish key](#) → others can use it
  - PGP for signing & encrypting email → recipient needs PGP

# Overview

- Introduction
- Internet security
- Database access control
- How to hack a database

# Database Access Control

- A **security policy** specifies **who** is authorized to do **what**
- A **security mechanism** allows us to **enforce** a chosen security policy
- Two main mechanisms at DBMS level:
  - Discretionary access control (=security at users' discretion)
  - Mandatory access control (=security enforced)

# Discretionary Access Control

- **concept** of access rights or **privileges** for objects (tables and views), and **mechanisms** for giving users privileges (and revoking privileges)
- **Creator** of a table or a view automatically gets **all** privileges on it
  - DMBS keeps track of who subsequently gains & loses privileges
  - Allows only requests from users with necessary privileges (at request time)

# GRANT Command

GRANT **privileges** ON object TO users [WITH GRANT OPTION]

- The following **privileges** can be specified:
  - **SELECT**: Can read all columns (incl those added later via ALTER TABLE command)
  - **INSERT(col-name)**: Can insert tuples with non-null or non-default values
    - *INSERT means same right with respect to all columns*
  - **DELETE**: Can delete tuples
  - **REFERENCES (col-name)**: Can define foreign keys (other tables) to this column
- If a user has a privilege with the GRANT OPTION, can pass privilege on to other users (with or without passing on the GRANT OPTION)
- Only owner can execute CREATE, ALTER, and DROP

# GRANT and REVOKE of Privileges

- GRANT INSERT, SELECT ON Sailors TO Horatio
  - Horatio can query Sailors or insert tuples into it
- GRANT DELETE ON Sailors TO Yuppy WITH GRANT OPTION
  - Yuppy can delete tuples, and also authorize others to do so
- GRANT UPDATE (rating) ON Sailors TO Dustin
  - Dustin can update (only) the rating field of Sailors tuples
- GRANT SELECT ON ActiveSailors TO Guppy, Yuppy
  - This does NOT allow the 'uppies to query Sailors directly!
- **REVOKE** cascades: When a privilege is revoked from X, it is also revoked from all users who got it solely from X

- Views can be used to present necessary information (or a summary), while hiding details in underlying relation(s)
  - Given ActiveSailors, but not Sailors or Reserves, we can find sailors who have a reservation, but not the bid's of boats that have been reserved
- Creator of view has a privilege on the view if (s)he has the privilege on all underlying tables
- Together with GRANT/REVOKE commands, **views are a very powerful access control tool**

# Security to the Level of a Field!

- Can create a view that only returns one field of one tuple (How?)
- Then grant access to that view accordingly
- Allows for **arbitrary granularity** of control, but:
  - Clumsy to specify, though this can be hidden under a good UI
  - Performance is unacceptable if we need to define field-granularity access frequently
    - *Too many view creations and look-ups*

# Role-Based Authorization

- In SQL-92, privileges were actually assigned to **authorization ids**, which can denote a single user or a group of users
- In SQL:1999 (and in many current systems), privileges are assigned to **roles**
  - Roles can then be granted to users and to other roles
  - Reflects how real organizations work
  - Illustrates how standards often catch up with “de facto” standards embodied in popular systems

# Mandatory Access Control

- Based on system-wide policies that cannot be changed by individual users
  - Each **DB object** is assigned a **security class**
  - Each **subject** (user or user program) is assigned a **clearance** for a security class
  - Rules based on security classes and clearances govern who can read/write which objects
- Most commercial systems do not support mandatory access control
- Versions of some DBMSs do support it; used for specialized (e.g., defence) applications

# Why Mandatory Control?

- Discretionary control has some flaws, e.g., the **Trojan horse problem**:
  - Dick creates table Horsie and gives INSERT privileges to Justin (who doesn't know about this)
  - Dick modifies the code of an application program used by Justin to additionally write some secret data to table Horsie
  - Now, Dick can see the secret data
- modification of code is beyond DBMS's control,  
but can **prevent use of the database as channel** for secret information

# Bell-LaPadula Model

- Objects
  - tables, views, tuples, ...
- Subjects
  - users, user programs, ...
- **Security classes:**  $TS > S > C > U$ 
  - Top secret (TS), secret (S), confidential (C), unclassified (U)
- Each object and subject is assigned a class
  - **Simple Security Property:**  
Subject S can **read** object O only if  $\text{class}(S) \geq \text{class}(O)$
  - **\*-Property:**  
Subject S can **write** object O only if  $\text{class}(S) \leq \text{class}(O)$

# Bell-LaPadula Model: Intuition

- Idea: ensure that
  - information can only be read from higher to lower security levels
  - Information can only be written from lower to higher security level
- Ex: Dick has security class C, Justin has class S, secret table has class S
  - Dick's table, **Horsie**, has Dick's clearance, C
  - Justin's application has his clearance, S
  - So, Justin's program (modified by Dick) cannot write into table **Horsie**
- Mandatory access control rules are applied **in addition** to any discretionary controls that are in effect

# Multilevel Relations

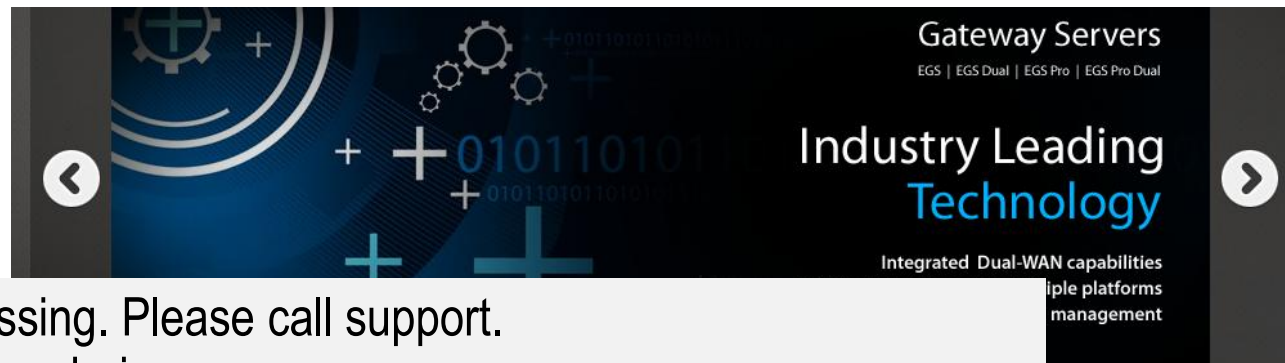

<u>bid</u>	bname	color	class
101	Salsa	Red	S
102	Pinto	Brown	C

- Users with S and TS clearance will see both rows
- user with C will only see the 2nd row
- user with U will see no rows
- ISSUE: If user with C tries to insert (101,Pasta,Blue,C):
  - Allowing insertion violates key constraint
  - Disallowing insertion tells user that there is another object with key 101 that has a class > C!
  - Problem resolved by treating class field as part of key

# Overview

- Introduction
- Internet security
- Database access control
- How to hack a database

# How to Expose Yourself

An error occurred during processing. Please call support.  
Lost connection to MySQL server during query  
SQL: select count(\*) from LoginsActive where MacAddress='\00:21:70:6E:04:AE\  
and MacAddress!=\'\' and Iface=\'br0\' and PropertyID=\'51225\  
IP:sql.ethostream.com  
DBU:remote  
DB:

OK, that was in 2011.

# Mom 's a Hacker

[found by: Prashant Vaibhav]

- SQL injection generalizes to: **Command injection**
  - ...usually by abusing **data** paths as **command** paths
- Ex: buffer overflow attack

```
{ char inputData[11];  
  char command;  
  switch (command)  
  {  
    case `s`: executeSelect( inputData ); break;  
    case `u`: executeUpdate( inputData ); break;  
    case `i`: executeInsert( inputData ); break;  
    case `d`: executeDelete( inputData ); break;  
    case `n`: detonateNuke(); break;  
  }  
}
```

# SW Reasons for Service Attacks

- Missing input validation
  - Design errors
  - Boundary conditions
  - Exception handling
  - Access validation
- 
- *Red = targets with increasing stats*
    - See also: OWASP Top 10

Vulnerability trends [Mitre]  
(XSS = cross-site scripting)

# Common Internet Attacks

- spear-phishing
  - = acquire information (usernames, passwords, CC details, ...) by **masquerading** as a trustworthy entity
- man in the middle (→ eavesdropping)
  - = attacker **makes independent connections** with victims, relays messages between them → victims believe they talk directly to each other
  - attacker intercepts all messages + injects new ones
- watering-hole
  - = attack group:  
Guess / observe sites which group often uses;  
infect these; eventually, some will get infected.

Dear valued customer of TrustedBank,

We have recieved notice that you have recently attempted to withdraw the following amount from your checking account while in another country: \$135.25.

If this information is not correct, someone unknown may have access to your account. As a safety measure, please visit our website via the link below to verify your personal information:

<http://www.trustedbank.com/general/custverifyinfo.asp>

Once you have done this, our fraud department will work to resolve this discrepancy. We are happy you have chosen us to do business with.

Thank you,  
TrustedBank

# Biggest Identity Leak to Date

- Discovered by Hold Security, reported in the New York times (Aug 5, 2014)
- 420,000 websites compromised, 1.2 billion user password data, 500 million e-mail addresses
- presumably bots carrying out automated SQL injection attacks
- PS: <https://sec.hpi.uni-potsdam.de/leak-checker/>

# Afterthoughts: Security and Software Engineering

- Additional security related engineering principles, such as: [Neil Daswani]
  - least privilege
    - *No more rights for any app than absolutely necessary*
  - fail-safe stance
    - *Always return to safe, stable state, after any kind of deviation*
  - protecting against weakest link
    - *Rank vulnerability of components, pay particular attention to “champions”*
- 3 P **security management**: Process, People, Probing your defences

*mobile apps?*
